Problems and Homeworks

- Use a line (hyperplane in \mathbb{R}^n) $a^T x + b = 0$, hence the followings must be satisfied:

$$a^T x_i + b > 0, i = 1, \dots, N \text{ and } a^T y_j + b < 0, j = 1, \dots, M.$$

- Since the strict inequalities are homogeneous in a and b , they are feasible iff the set of nonstrict linear inequalities:

$$a^T x_i + b > 1, i = 1, \dots, N \text{ and } a^T y_j + b < -1, j = 1, \dots, M.$$

- The classification is better if having $u_i, v_j \geq 0$ such that:

$$a^T x_i + b > 1 - u_i \text{ and } a^T y_j + b < -1 + v_j,$$

where $i = 1, \dots, N$ and $j = 1, \dots, M$.

- The best one should be at minimizer of $\sum_{i=1}^N u_i + \sum_{j=1}^M v_j$.

- Recall the standard form of LP:

$$\begin{aligned} \min_x \quad & c^T x \\ \text{s.t.} \quad & Ax = b, \\ & x \geq 0, \end{aligned} \tag{5}$$
$$\tag{6}$$

where $c \in \mathbb{R}^n$, A is an $m \times n$ matrix with full row rank, and $b \in \mathbb{R}^m$.

- A polyhedron is a set of the form $\{x \in \mathbb{R}^n | Bx \geq d\}$ for some matrix B .
- Let $P \in \mathbb{R}^n$ be a given polyhedron. A vector $x \in P$ is an extreme point of P if there does not exist $y, z \in P$, and $\lambda \in (0, 1)$ such that $x = \lambda y + (1 - \lambda)z$.

Integer Linear Program (ILP)

- An integer linear program is a linear program where variables are constrained to be integers.

$$\min_x c^T x$$

s.t.

$$Ax = b, \quad (10)$$

$$x \geq 0 \text{ and } x \in \mathbb{Z}^n. \quad (11)$$

Question

Why do we consider the problem with only equality constraints but not inequality ones?

Remark

Often a mix is desired of integer and non-integer variables, called Mixed Integer Linear Programs (MILP).

Problems and Homeworks

- Let $S = \{x \in \mathbb{R}^n | Ax = b, x \geq 0\}$, the feasible set of LP. Since A is full row rank, if the feasible set is not empty, then we must $m \leq n$. Without loss of generality, we assume that $m < n$.
- Let $A = (B, N)$, where B is an $m \times m$ matrix with full rank, i.e., $\det(B) \neq 0$. Then, B is called a *basis*.
- Let $x = \begin{pmatrix} x_B \\ x_N \end{pmatrix}$. We have $Bx_B + Nx_N = b$. Setting $x_N = 0$ gives $x_B = B^{-1}b$. $x = \begin{pmatrix} B^{-1}b \\ 0 \end{pmatrix}$ is called a *basic solution*. x_B is called *basic variables*, x_N is called *nonbasic variables*.
- If the basic solution is also feasible, this is, $B^{-1}b \geq 0$, then $x = \begin{pmatrix} B^{-1}b \\ 0 \end{pmatrix}$ is said to be a *basic feasible solution*.

- $\hat{x} \in S$ is an extreme point of S if and only if \hat{x} is a basic feasible solution.
- Two extreme points are *adjacent* if they differ in only one basic variable.

Theorem (Basic theorem of LP)

Consider the linear program $\min\{c^T x \mid Ax = b, x \geq 0\}$. If S has at least one extreme point and there exists an optimal solution, then there exists an optimal solution that is an extreme point.

- The feasible set of standard form linear program has at least one extreme point.
- Therefore, we claim that the optimal value of a linear program is either $-\infty$, or is attained at an extreme point (basic feasible solution) of the feasible set.

A Naive Algorithm for Solving Linear Program

- Let $\min\{c^T x \mid Ax = b, x \geq 0\}$ be a bounded linear program.
- Enumerate all bases $\mathcal{B} \in \{1, 2, \dots, n\}$, $\binom{m}{n} = O(n^m)$, too many.
- Compute associated basic solution $x = \begin{pmatrix} B^{-1}b \\ 0 \end{pmatrix}$.
- Return the one which has largest objective function value among the feasible basic solutions.
- Running time is $O(n^m \cdot m^3)$.

Problems and Homeworks

- Simplex method was invented by George Dantzig (1914–2005) (father of linear programming).
- Suppose we have a basic feasible solution $\hat{x} = \begin{pmatrix} B^{-1}b \\ 0 \end{pmatrix}$, $A = (B, N)$.
- Let $x \in S$ be any feasible solution of the LP. Let $x = \begin{pmatrix} x_B \\ x_N \end{pmatrix}$ and $c = \begin{pmatrix} c_B \\ c_N \end{pmatrix}$. Then, $Bx_B + Nx_N = b$ and $x_B = B^{-1}b - B^{-1}Nx_N$. We have
$$\begin{aligned} c^T x &= c_B^T x_B + c_N^T x_N \\ &= c_B^T B^{-1}b - c_B^T B^{-1}Nx_N + c_N^T x_N \\ &= c^T \hat{x} + (c_N^T - c_B^T B^{-1}N)x_N. \end{aligned}$$
- Let $r_N = (c_N^T - c_B^T B^{-1}N)$, called *reduced cost*. If $r_N \geq 0$, then $c^T x \geq c^T \hat{x}$ and the current extreme point \hat{x} is *optimal*.

Problems and Homeworks

- Otherwise, there must exist an $r_i < 0$, we can let current nonbasic variable x_i become a basic one $x_i > 0$ (*entering variable*).
- Suitably choosing basic variable to become a nonbasic one (*leaving variable*), we can get a new basic feasible solution whose objective value is less than that of the current basic feasible solution \hat{x} .
- Geometrically, the simplex method moves from one extreme point to one of its *adjacent* extreme point.
- Since there are only a finite number of extreme points, the method terminates finitely at an *optimal solution* or detects that the problem is *infeasible* or it is *unbounded*.

Problems and Homeworks

- Step 0: Compute an initial basis B and the basic feasible $B^{-1}b$ solution $x = \begin{pmatrix} B^{-1}b \\ 0 \end{pmatrix}$.
- Step 1: if $r_N = (c_N^T - c_B^T B^{-1}N) \geq 0$, **stop**, x is an optimal solution. Otherwise **goto** Step 2.
- Step 2: Choose j satisfying $c_i^T - c_B^T B^{-1}a_j < 0$, if $\bar{a}_j = B^{-1}a_j \leq 0$, **stop**, the LP is infeasible. Otherwise, **goto** Step 3.
- Step 3: compute the step size

$$\lambda = \min\left\{\frac{\bar{b}_i}{\bar{a}_{ij}} \mid \bar{a}_{ij} > 0\right\} = \frac{\bar{b}_r}{\bar{a}_{rj}}$$

Let $x := x + \lambda d_j$, where $d_j = \begin{pmatrix} B^{-1}a_j \\ e_j \end{pmatrix}$. **goto** Step 1.

x_B	x_N	rhs
B	N	b
c_B^T	c_N^T	0

It implies that

x_B	x_N	rhs
I	$B^{-1}N$	$B^{-1}b$
0	$c_N^T - c_B^T B^{-1}N$	$-c_B^T B^{-1}b$

Simplex Method: example (cont.)

- Choose the initial basis to be $B = (a_1, a_3, a_4)$, we have basic $x_B = (x_1, x_3, x_4)^T$. The simplex tableau is then

x_1	x_2	x_3	x_4	x_5	rhs
0	3	1	0	$-\frac{1}{2}$	$7\frac{1}{2}$
0	-4	0	1	$2\frac{1}{2}$	$2\frac{1}{2}$
1	1	0	0	$-\frac{1}{2}$	$3\frac{1}{2}$
0	5	0	0	$-\frac{7}{2}$	$24\frac{1}{2}$

- The basic feasible solution is $x_B = (x_1, x_3, x_4)^T = (3\frac{1}{2}, 7\frac{1}{2}, 2\frac{1}{2})^T$.
- Since $r_5 = -\frac{7}{2} < 0$, x_5 is chosen entering variable.
 $\lambda = \frac{2\frac{1}{2}}{2\frac{1}{2}} = 1$, then x_4 is leaving variable. The new basic variable should be $x_B = (x_1, x_3, x_5)^T$. The new tableau is obtained as below.

x_1	x_2	x_3	x_4	x_5	rhs
0	$\frac{11}{5}$	1	$\frac{1}{5}$	0	8
0	$-\frac{8}{5}$	0	$\frac{2}{5}$	1	1
1	$\frac{1}{5}$	0	$\frac{1}{5}$	0	4
0	$-\frac{7}{3}$	0	$\frac{7}{5}$	0	28

Problems and Homeworks

Simplex Method: example (cont.)

- Similarly, choose x_2 as the entering variable, then $\lambda = \min\{\frac{8}{11/5}, \frac{4}{1/5}\} = \frac{40}{11}$. Hence x_3 is leaving variable.

Therefore, the tableau is

x_1	x_2	x_3	x_4	x_5	rhs
0	1	$\frac{5}{11}$	$\frac{1}{11}$	0	$\frac{40}{11}$
0	0	$\frac{8}{11}$	$\frac{6}{11}$	1	$\frac{75}{11}$
1	0	$-\frac{1}{11}$	$\frac{2}{11}$	0	$\frac{36}{11}$
0	0	$\frac{3}{11}$	$\frac{16}{11}$	0	$30\frac{2}{11}$

- Since $r_N = (\frac{3}{11}, \frac{16}{11}) \geq 0$, the current basic feasible solution $x = (\frac{36}{11}, \frac{40}{11}, 0, 0, \frac{75}{11})^T$ is optimal with the optimal value is $-30\frac{2}{11}$.

Numerical Example 2 – LP Relaxation: $x_1 = 1, x_2 = 1$

$$\max(Z = 14 + 6x_3 + 4x_4) \quad (80)$$

$$S.t. \quad 5x_3 + 2x_4 \leq 1$$

$$x_3 + x_4 \leq 1$$

$$0 \leq x_3 \leq 1$$

$$0 \leq x_4 \leq 1$$

- With $x_3 = 0$, $Z = 16$ is still feasible solution at $(1, 1, 0, 0.5)$
 - With $x_4 = 0$, $(1, 1, 0, 0)$, $Z = 14$ (new optimal solution)
 - With $x_4 = 1$, $(1, 1, 0, 1)$ is not feasible

\Rightarrow The current best solution $(1, 1, 0, 0)$ with $Z = 14$ is the optimal solution.

How to Branch?

- We want to divide the current problem into two or more subproblems that are easier than the original. A commonly used branching method:

$$x_i \leq \lfloor x_i^* \rfloor, x_i \geq \lceil x_i^* \rceil,$$

where x_i^* is a fractional variable.

- Which variable to branch? A commonly used branching rule: Branch the most fractional variable.
- We would like to choose the branching that minimizes the sum of the solution times of all the created subproblems.
- How do we know how long it will take to solve each subproblem?
 - Answer: We don't.
 - Idea: Try to predict the difficulty of a subproblem.
- A good branching rule: The value of the linear programming relaxation changes a lot.

Which Node to Select?

- An important choice in branch and bound is the strategy for selecting the next subproblem to be processed.
- Goals: (i) Minimizing overall solution time; (ii) Finding a good feasible solution quickly.
- Some commonly used search strategies:
 - Best First,
 - Depth-First.

Numerical Example 2

Strategy and Steps

Exercise: 0-1 KP

Remarks

How to Branch?

Which Node to Select?

Rule of Fathoming

Software for ILP

Problems and Homeworks

The Best First Approach

- One way to minimize overall solution time is to try to minimize the size of the search tree. We can achieve this by choosing the subproblem with the *best bound* (lowest lower bound if we are minimizing).
- *Drawbacks* of Best First
 - Doesn't necessarily find feasible solutions quickly since feasible solutions are "more likely" to be found deep in the tree.
 - Node setup costs are high. The linear program being solved may change quite a bit from one node evaluation to the next.
 - Memory usage is high. It can require a lot of memory to store the candidate list, since the tree can grow "broad".

Which Node to Select?

Rule of Fathoming

Software for ILP

Problems and Homeworks

The Depth-First Approach

- The depth first approach is to always choose the deepest node to process next. Just dive until you prune, then back up and go the other way.
- This avoids most of the problems with best first: The number of candidate nodes is minimized (saving memory). The node set-up costs are minimized.
- LPs change very little from one iteration to the next. Feasible solutions are usually found quickly.
- *Drawback*: If the initial lower bound is not very good, then we may end up processing lots of non-critical nodes.
- Hybrid Strategies: Go depth-first until you find a feasible solution, then do best-first search.

A subproblem is fathomed when

- ① The relaxation of the subproblem has an optimal solution with $z < z^*$ where z^* is the current best solution;
- ② The relaxation of the subproblem has no feasible solution;
- ③ The relaxation of the subproblem has an optimal solution that has all integer values (or all binary if it is an BIP).

- Matlab optimization toolbox: [bintprog](#) – a built-in function for mixed integer linear programming.
- Some of softwares which are proprietary but *free for academic use*:

Transportation Problem — Linear Programming Model

Statement of an instance

Suppose a company has 2 factories $\mathcal{F}_1, \mathcal{F}_2$ and 9 retail outlets $\mathcal{R}_1, \dots, \mathcal{R}_9$:

- the total supply of the product from each factory \mathcal{F}_i is a_i ;
- the total demand for the product at each outlet \mathcal{R}_j is b_j ;
- The cost of sending one unit of the product from factory \mathcal{F}_i to outlet \mathcal{R}_j is equal to c_{ij} ,

where $i = 1, 2$ and $j = 1, 2, \dots, 9$.

The problem is to determine a transportation scheme between the factories and the outlets so as to minimize the total transportation cost, subject to the specified supply and demand constraints..

Knapsack Problems — Integer Linear Programming Model

There are many different knapsack problems. The first and classical one is the binary knapsack problem.

Binary (0-1) knapsack problem

A tourist is planning a tour in the mountains. He has a lot of objects which may be useful during the tour. For example ice pick and can opener can be among the objects. We suppose that

- Each object has a positive value and a positive weight, the value is the degree of contribution of the object to the success of the tour;

- Similarly $v_j x_j$ is the value of the object on the tour. The total weight in the knapsack is

$$\sum_{j=1}^n v_j x_j$$

which may not exceed the weight limit.

- Hence the mathematical form of the problem is as follows.

$$\max_x \sum_{j=1}^n v_j x_j \quad (84)$$

subject to

$$\sum_{j=1}^n w_j x_j \leq b, \quad (85)$$

$$x_j = 0 \text{ or } 1, \quad j = 1, \dots, n. \quad (86)$$

Solving the problem in this case

- The difficulty of the problem is caused by the integrality requirement. If constraint (86) is substituted by the relaxed constraint, i.e. by

$$0 \leq x_j \leq 1, \quad j = 1, \dots, n, \quad (87)$$

then the Problem (84), (85), and (87) is a linear programming problem. (87) means that not only a complete object can be in the knapsack but any part of it.

Theorem

Suppose: v_j, w_j ($j = 1, \dots, n$)-all positive, and satisfies

$$\frac{v_1}{w_1} \geq \frac{v_2}{w_2} \geq \dots \geq \frac{v_n}{w_n}. \quad (88)$$

Then there is an index p ($1 \leq p \leq n$) and an optimal sol. \mathbf{x}^* s.t.

$$x_1^* = x_2^* = \dots = x_{p-1}^* = 1, \quad x_{p+1}^* = x_{p+2}^* = \dots = x_{p+1}^* = 0.$$

Solving the problem in this case

- The difficulty of the problem is caused by the integrality requirement. If constraint (86) is substituted by the relaxed constraint, i.e. by

$$0 \leq x_j \leq 1, \quad j = 1, \dots, n, \quad (87)$$

then the Problem (84), (85), and (87) is a linear programming problem. (87) means that not only a complete object can be in the knapsack but any part of it.

- Moreover in this special case, it is not necessary to apply the simplex method or any other LP algorithm to solve it, as its optimal solution is described by

Theorem

Suppose: v_j, w_j ($j = 1, \dots, n$)-all positive, and satisfies

$$\frac{v_1}{w_1} \geq \frac{v_2}{w_2} \geq \dots \geq \frac{v_n}{w_n}. \quad (88)$$

Then there is an index p ($1 \leq p \leq n$) and an optimal sol. \mathbf{x}^* s.t.

$$x_1^* = x_2^* = \dots = x_{p-1}^* = 1, \quad x_{p+1}^* = x_{p+2}^* = \dots = x_{p+1}^* = 0.$$

- Notice that there is only at most one non-integer component in \mathbf{x}^* . This property will be used at the numerical calculations.

Problem statement

Given a grid of 9×9 , the grid is divided into 9 subgrids of 3×3 . Some cells of subgrids are filled by digits in $\{1, 2, \dots, 9\}$. The objective is to fill remaining cells such that

- each column, each row, and each subgrid that compose the grid, contain all of the digits from 1 to 9.

Problem statement

Let $G = (V, E)$ be a complete graph, where $V = 0, \dots, n$ is the set of vertices and E is the set of edges.

- We assume that vertex 0 denotes the depot, whereas vertex $i = 1, \dots, n$ is customer.
- A nonnegative value, denoted by c_{ij} , is the *cost* associated with each edge of G that connects vertex i and j .
- Let $S \subseteq V$, we denote by $r(S)$ the minimum number of vehicles required for all customers in S .

Given a positive integer number k , the capacitated vehicle routing problem is asked for seeking k simple routes that *minimizing a cost function of the sum of cost of edges of the routes*, and *satisfying simultaneously*:

- (i) each route starts at the depot vertex,
- (ii) each customer belongs exactly one route,
- (iii) the sum of demands of the vertices visited by a route is always lower than the capacity C of the vehicle.
